

Dear Reviewer, this letter has no formal letterhead, no centred company name, no logo, and no horizontal rule along the top of the page. It is meant to exercise the negative path of the letterhead detector: there is no ink-then-whitespace pattern in the top third of the page, so the smart-boundary scan should not lock onto any particular y-coordinate as the lower edge of a letterhead block.

The intent here is to produce a document that looks the way many informal letters and memos look in practice: a salutation followed immediately by paragraphs of body text, with no decorative header separating the sender block from the message itself. Real-world inputs of this shape are common enough that the extractor must handle them without hallucinating a letterhead region.

We continue with several more lines of body text to fill the page and ensure that the detector cannot rely on a short document as a shortcut. The body wraps around natural paragraph breaks and uses the same 11pt Helvetica face throughout, which means the ink profile across the top of the page is roughly uniform rather than showing the sharp transitions characteristic of a letterhead.

In the absence of any reliable ink-to-whitespace transition, the detector is expected either to fall back to the default 18% crop with low confidence or to return null and let downstream consumers decide. This fixture deliberately makes either outcome defensible.

Sincerely,

John Doe
